

LANDVERIFYCM

Frontend & Mobile Development

How the citizen-facing experience turns verified records into clear, practical decisions

TEAM MEMBER 01

**NKAM
TITCHA**

01 PROJECT IN ONE VIEW

LandVerifyCM is a bilingual platform built to reduce land fraud and uncertainty in Cameroon. Citizens and professionals search the registry and review a parcel's status, location and ownership history; authorized administrators maintain records. The interface connects to the Express API, where verification happens, and presents the result clearly.

02 MY RESPONSIBILITY

As Frontend Developer, I built the interaction layer for the React website and Expo/React Native client. My work turns API data into responsive screens, protects role-specific routes, validates input and keeps the experience consistent in English and French.

03 REACT WEB FRONTEND

A guided citizen journey

From first search to an informed view of a parcel

- **Find records.** Users search by title number, parcel ID or owner name, or browse by quarter.
- **Understand results.** Cards and colour-coded badges show Valid, Suspicious or Duplicate status alongside loading, empty and error states.
- **Inspect evidence.** Details include area, land use, approval year, GPS coordinates, ownership history and documents.
- **See the location.** Leaflet maps place parcels on OpenStreetMap, offer street/satellite layers and copy coordinates.

Secure administration

Tools for trusted staff to keep the public registry useful

- **Access control.** Registration, login, password recovery and profile screens support users; protected routes restrict management to administrators.
- **Record management.** Admins upload, edit, deactivate and review parcels with GPS points, ownership chains and PDF/image evidence.
- **Usability.** Form validation, toast feedback, motion and responsive Tailwind layouts simplify complex tasks.

Mobile Access & Public Impact

One shared service, presented for practical use on phones and in a browser

04 EXPO / REACT NATIVE CLIENT

Mobile-first access

The same core service is available through Android, iOS and a browser build

- **Navigate quickly.** Top and bottom navigation reach Home, Search, Browse, About and Profile; admins also receive management screens.
- **Verify on the move.** Users search, inspect status, GPS maps and ownership history, then open Google Maps.
- **Handle documents.** Authenticated users download and share evidence; admins select up to five PDF/JPG/PNG files.
- **Stay secure.** JWT sessions use SecureStore on native devices, role checks guard admin routes, and friendly errors explain failures.

05 LANGUAGES AND TOOLS — AND WHY

React + TypeScript

Reusable, typed components reduce UI errors and ease web/mobile maintenance.

React Router + Context

Clear routes plus shared authentication and English/French state across the web application.

Expo + React Native

One codebase targets Android, iOS and the browser with a native-style experience.

Vite + Tailwind CSS

Fast web builds and responsive layouts for phones, tablets and desktops.

Leaflet + OpenStreetMap

GPS parcels become understandable visual locations, with street/satellite views on the web.

SecureStore + Expo tools

Protects sessions and supports document picking, downloading, sharing and embedded maps.

06 VALUE FOR CAMEROON

PUBLIC BENEFIT

Phone and web access helps people check a parcel before paying, compare title information with its GPS location and notice suspicious or duplicate records earlier.

TRUST THROUGH CLARITY

Bilingual screens widen access; visible status, history and evidence support informed discussions with land offices and professionals. The platform supports due diligence; it does not replace official legal checks.

07 PRESENTATION CLOSE

My contribution makes the project’s verification work **visible, understandable and usable**—especially for people accessing the service from a mobile phone.
